MOTIVATION

The French Brazilian cooperation between INCT-APA/UFRJ (Brasil) and UMR 5805 EPOC/UB (France) consists in investigating the role of biodiversity on the mineralization of organic matter (OM) in Admiralty Bay sediments (King George Island, Antarctic Peninsula). The characterization of relationships between (1) the diversity of benthic fauna, (2) sediment bioturbation processes, and (3) biogeochemical fluxes at the sediment-water interface is essential to better understand the consequences of a change in benthic biodiversity resulting from global changes on the ecological and biogeochemical functioning of Antarctic coastal ecosystems.

STRATEGY – APPROACH

The link between the diversity of benthic fauna, bioturbation processes and biogeochemical fluxes is investigated by using a hierarchical approach, which consider that the intensity of OM mineralization results from the superposition of the effects of different types of factors (Figure 1).

The first stage of this work aims at assessing the spatial variability of the main characteristics of sedimentary OM and its lability.

STUDY SITE – SAMPLING

The Admiralty Bay is located on the southern coastline of King George Island (South Shetland Islands) close to the northern tip of the Antarctic Peninsula (Figure 2).

Sediments cores were collected during the 2012 austral summer. Organic carbon (OC) and total nitrogen (N), total and enzymatically hydrolysable amino acids (THAA, EHAA), chloropigments (and their degradation products) and δ13C of OC were measured in the top sediment layer (~0-1 cm) at 53 stations located within the three inlets of Admiralty Bay. These samples are the only ones that escaped the destruction of the Brazilian Station, Comandante Ferraz, in February 2012.

RESULTS

Results clearly show an important spatial variability of OM descriptors throughout the Admiralty Bay. Based on the main characteristics of sedimentary organic matter, the inlets are significantly different (ANOSIM, Global R=0.24, p<0.001). Organic C contents were quite low in the different inlets of Admiralty Bay as observed in other Antarctic areas although the highest contents were measured in areas enriched in macroalgae and close to the Brazilian Scientific Station (Table 1). Total N had a similar pattern with levels 3 times higher close to the Brazilian Station. The sediments consisted mainly of silty muds but fine sands have also been found in some areas in the vicinity of glaciers or at the entrance of inlets. However, the observed differences in OM descriptors cannot be only explained by sediment grain size.

The C/N ratios and δ13C values suggest the occurrence of marine OM although a contribution of continental inputs and/or degraded material can be locally observed, as for instance in front of the Glacier Tokarski in the Mackellier inlet. This is coherent with the high values of qualitative descriptors (PRI and EHAA/THAA), which indicate a high (1) lability of sedimentary OM, and (2) spatial variability associated to its origin.

Component 1 of the PCA was clearly associated with quantitative descriptors of OM, which correlated negatively with D50 and C/N and positively with δ13C whereas the quality and freshness of chloropigments (Chl, PRI) were greatly associated to Component 2. The qualitative descriptors of the bulk OM (C/N, δ13C) are negatively correlated to the freshness of vegetal OM, indicating its low contribution to the bulk fraction. Interestingly, all stations of both Martel and Mackellar inlets that were well described by Component 2 are located all around the Keller peninsula, suggesting a similar source of fresh and labile plant material.

Ours results show (1) a low OC content in the surface sediments of Admiralty Bay as observed in other Antarctic zones, (2) a strong spatial heterogeneity of main descriptors of sedimentary OM, (3) the occurrence of labile sedimentary organic with a major contribution of marine OM, and (4) that the fresh and labile plant material was mainly located around the Keller peninsula (Mackeller and Martel inlets). This preliminary work was essential to refine the sampling strategy for the field trip scheduled in Jan. 2016. Our next field work is scheduled in the upwelling region of Cabo Frio (Brasil) in January & July 2015.
